# Timing problems in vehicle routing

- General effort dedicated to better address rich vehicle routing problems involving many side constraints and attributes
- Observation: many rich VRPs are hard because of their time features: (single, soft, or multiple) time windows, time-dependent, flexible or stochastic travel times, various time-dependent costs, break scheduling...
- Timing subproblems: similar formulations in various domains: VRP, scheduling, PERT, resource allocation, isotone regression, telecommunications...
- Cross-domain analysis of timing problems and algorithms:
  - ► T. Vidal, T. G. Crainic, M. Gendreau, and C. Prins. A Unifying View on Timing Problems and Algorithms. Submitted & revised to Networks. Tech. Rep. CIRRELT 2011-43.

• Four different applications

E/T scheduling

ship speed opt.

isotonic regression

• VRP with soft time windows. Optimizing arrival times for a given sequence of visits  $\sigma$ :

$$\min_{\mathbf{t} \geq \mathbf{0}} \ \alpha \sum_{i=1}^{|\sigma|} \max\{e_{\sigma(i)} - t_{\sigma(i)}, 0\} + \beta \sum_{i=1}^{|\sigma|} \max\{t_{\sigma(i)} - t_{\sigma(i)}, 0\}$$
 (1.1)

s.t. 
$$t_{\sigma(i)} + \delta_{\sigma(i)\sigma(i+1)} \le t_{\sigma(i+1)}$$

$$1 \le i < |\sigma| \tag{1.2}$$

• Four different applications

E/T scheduling

ship speed opt.

isotonic regression

• **E/T scheduling**. Optimizing processing dates for a given sequence of visits  $\sigma$ :

$$\min_{\mathbf{t} \geq \mathbf{0}} \sum_{i=1}^{|\sigma|} \alpha_i \max\{d_{\sigma(i)} - t_{\sigma(i)}, 0\} + \sum_{i=1}^{|\sigma|} \beta_i \max\{t_{\sigma(i)} - d_{\sigma(i)}, 0\}$$
 (1.3)

s.t. 
$$t_{\sigma(i)} + p_{\sigma(i)} \le t_{\sigma(i+1)}$$

$$1 \le i < |\sigma| \tag{1.4}$$

• Four different applications

#### VRPTW

E/T scheduling

ship speed opt.

isotonic regression

• Ship speed optimization. Optimizing leg speeds to visit a sequence of locations  $\sigma$ :

$$\min_{\mathbf{t} \ge \mathbf{0}} \sum_{i=1}^{|\sigma|-1} d_{\sigma(i)\sigma(i+1)} \hat{c} \left( \frac{d_{\sigma(i)\sigma(i+1)}}{t_{\sigma(i+1)} - t_{\sigma(i)}} \right) \tag{1.5}$$

s.t. 
$$t_{\sigma(i)} + p_{\sigma(i)} + \frac{d_{\sigma(i)\sigma(i+1)}}{v_{max}} \le t_{\sigma(i+1)}$$

$$1 \le i < |\sigma|$$

$$i < |\sigma|$$
 (1.6)

$$r_{\sigma(i)} \leq t_{\sigma(i)} \leq d_{\sigma(i)}$$

$$1 \le i \le |\sigma| \tag{1.7}$$

• Four different applications

E/T scheduling

ship speed opt.

isotonic regression

• Isotonic Regression. Given a vector  $\mathbf{N} = (N_1, \dots, N_n)$  of n real numbers, finding a vector of non-decreasing values  $\mathbf{t} = (t_1, \dots, t_n)$  as close as possible to  $\mathbf{N}$  according to a distance metric:

$$\min_{\mathbf{t}=(t_1,\dots,t_n)} \|\mathbf{t} - \mathbf{N}\| \tag{1.8}$$

s.t. 
$$t_i \leq t_{i+1}$$

$$1 \le i < n$$

## General Timing Problem

• Timing problems:

$$\min_{\mathbf{t} \ge \mathbf{0}} \sum_{F^x \in \mathcal{F}^{\text{OBJ}}} \alpha_x \sum_{1 \le y \le m_x} f_y^x(\mathbf{t}) \tag{1.10}$$

$$s.t. \quad t_i + p_i \le t_{i+1} \qquad 1 \le i < n \tag{1.11}$$

$$f_y^x(\mathbf{t}) \le 0$$
  $F^x \in \mathcal{F}^{\text{CONS}}, \ 1 \le y \le m_x$  (1.12)

- Continuous variables  $t_i$  following a **total order**.
- Additional features characterized by functions  $f_y^x(\mathbf{t})$  for  $y \in \{1, \dots, m_x\}$ , either in the objective or as constraints.
- Many names in the literature: scheduling, timing, projection onto order simplexes, optimal service time problem...

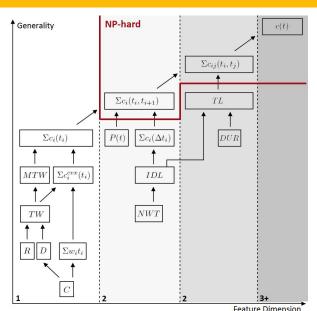

#### Features

#### • Rich vehicle routing problems can involve various timing features

$\begin{array}{ c c c c c } \hline W & Weights $w_i$ & $f_i(\mathbf{t}) = w_i t_i$ \\ D & Deadlines $d_i$ & $f_i(\mathbf{t}) = (t_i - d_i)^+$ \\ R & Release dates $r_i$ & $f_i(\mathbf{t}) = (r_i - t_i)^+$ \\ Time windows & $f_i(\mathbf{t}) = (r_i - d_i)^+$ \\ TW & Time windows & $f_i(\mathbf{t}) = (t_i - d_i)^+$ \\ TW_i = [r_i, d_i] & +(r_i - t_i)^+$ \\ MU & Multiple TW & $f_i(\mathbf{t}) = \min_i [(t_i - d_{ik})^+$ \\ MTW_i = \cup [r_{ik}, d_{ik}] & +(r_{ik} - t_i)^+$ \\ +(r_{ik} - t_i)^+$ \\ Sc_i^{\text{CVX}}(t_i) & \text{General $c_i(t)$} & f_i(\mathbf{t}) = c_i^{\text{CVX}}(t_i) & 1 \\ DUR & Total dur. $\delta_{max}$ & $f(\mathbf{t}) = (t_n - \delta_{max} - t_1)^+$ \\ IDL & Idle time $\iota_i$ & $f_i(\mathbf{t}) = (t_{i+1} - p_i - t_i)^+$ \\ IDL & Time-dependent & $f_i(\mathbf{t}) = (t_{i+1} - p_i - t_i - t_i)^+$ \\ P(t) & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_j - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i + p_i(t_i) - t_{i+1})^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $f_i(\mathbf{t}) = (t_i - \delta_{ij} - t_i)^+$ \\ TL & Time-dependent & $t_i - t_i - t_i - t_i - t_i - t_i - t_i - $	Symbol	Parameters	Char. functions	ξ	Most frequent roles

#### Hierarchy of features

- These features can be classified within a hierarchy (using many-one linear reduction relationships between the associated timing problems)
- Features in the NP-hard area lead to NP-hard timing problems

## Re-optimization

- Some particular features have been extensively studied in various fields.
  - ▶ For example for the problem  $\{\Sigma c_i^{\text{CVX}}(t_i)|\ \emptyset\}$  30 algorithms from various domains (routing, scheduling, PERT, isotonic regression) were inventoried, based on only three main concepts.
- Key lines of research related to the resolution of series of similar timing problems within neighborhood searches, considering different sequences  $\sigma$ .

$$\min_{\mathbf{t} \ge \mathbf{0}} \quad \sum_{F^x \in \mathcal{F}^{\text{OBJ}}} \alpha_x \sum_{1 \le y \le m_x} f_y^x(\mathbf{t}) \tag{1.13}$$

s.t. 
$$t_{\sigma^k(i)} + p_{\sigma^k(i),\sigma^k(i+1)} \le t_{\sigma^k(i+1)} \quad 1 \le i < |\sigma|$$
 (1.14)

$$f_y^x(\mathbf{t}) \le 0$$
  $F^x \in \mathcal{F}^{\text{CONS}}, \ 1 \le y \le m_x \quad (1.15)$

# One particular problem

• Consider one particular timing problem with flexible travel times and deadlines:

$$\min_{\mathbf{t} \ge \mathbf{0}} \sum_{i=1}^{|\sigma|-1} c_i (t_{\sigma(i+1)} - t_{\sigma(i)})$$
 (2.1)

s.t. 
$$t_{\sigma(i)} + p_{\sigma(i)} + \frac{d_{\sigma(i)\sigma(i+1)}}{v_{max}} \le t_{\sigma(i+1)}$$
  $1 \le i < |\sigma|$  (2.2)  $t_{\sigma(i)} \le d_{\sigma(i)}$   $1 \le i \le |\sigma|$  (2.3)

$$t_{\sigma(i)} \le d_{\sigma(i)} \qquad 1 \le i \le |\sigma| \qquad (2.3)$$

$$t_{\sigma(|\sigma|)} = B \tag{2.4}$$

- It is a vehicle speed optimization problem with convex and **possibly heterogeneous** – cost/speed functions per leg.
- Direct applications related to:
  - ► Ship speed optimization (Norstad et al., 2011; Hvattum et al., 2013)
  - ► Vehicle routing with flexible travel time or pollution routing (Hashimoto et al., 2006; Bektas and Laporte, 2011)

# One particular problem

 Consider one particular timing problem with flexible travel times and deadlines:

$$\min_{\mathbf{t} \ge \mathbf{0}} \sum_{i=1}^{|\sigma|-1} c_i (t_{\sigma(i+1)} - t_{\sigma(i)})$$
 (2.5)

s.t. 
$$t_{\sigma(i)} + p_{\sigma(i)} + \frac{d_{\sigma(i)\sigma(i+1)}}{v_{max}} \le t_{\sigma(i+1)}$$
  $1 \le i < |\sigma|$  (2.6)

$$t_{\sigma(i)} \le d_{\sigma(i)} \qquad 1 \le i \le |\sigma| \qquad (2.7)$$

$$t_{\sigma(|\sigma|)} = B \tag{2.8}$$

- A quick reformulation
  - ▶ Waiting times can be modeled by additional activities with null cost
  - Change of variables  $x_i = t_{\sigma(i+1)} t_{\sigma(i)} p_{\sigma(i)} \frac{d_{\sigma(i)\sigma(i+1)}}{r}$
  - ▶ leads to...

#### A resource allocation problem

• A resource allocation problem with nested constraints (NESTED)

$$\min \quad f(\mathbf{x}) = \sum_{i=1}^{n} f_i(x_i) \tag{2.9}$$

s.t. 
$$0 \le x_i \le d_i$$
  $i \in \{1, ..., n\}$  (2.10)

$$\sum_{k=1}^{s[i]} x_k \le a_i \qquad i \in \{1, \dots, m-1\}$$
 (2.11)

$$\sum_{i=1}^{n} x_i = B \tag{2.12}$$

- ▶ Integer or continuous variables are considered here
- ▶ Travel time  $x_i$  on each leg, subject to a maximum bound  $d_i$ .
- ▶ Deadlines  $a_i$  on arrival time at some ports.
- ▶ Table s[] listing the indices of variables on which deadlines are applied. There may be less deadline constraints m than variables n.
- ► Final arrival date B.

## A resource allocation problem

• Without the nested constraints (2.16) ⇒ Standard resource allocation problem (Ibaraki and Katoh, 1988; Patriksson, 2008)

$$\min_{\mathbf{0} \le \mathbf{x} \le \mathbf{d}} \quad f(\mathbf{x}) = \sum_{i=1}^{n} f_i(x_i)$$
 (2.13)

s.t. 
$$\sum_{i=1}^{n} x_i = B$$
 (2.14)

▶ Interesting applications to search-effort allocation, portfolio selection, energy optimization, sample allocation in stratified sampling, capital budgeting, mass advertising, and matrix balancing, among others.

## A resource allocation problem

Various applications

$$\min_{\mathbf{0} \le \mathbf{x} \le \mathbf{d}} \quad f(\mathbf{x}) = \sum_{i=1}^{n} f_i(x_i)$$
 (2.15)

s.t. 
$$\sum_{k=1}^{s[i]} x_k \le a_i$$
  $i \in \{1, \dots, m-1\}$  (2.16)

$$\sum_{i=1}^{n} x_i = B \tag{2.17}$$

- With the nested constraints, additional applications to
  - ▶ Project crashing (Talbot, 1982)
  - ▶ Production and resource planning (Bellman et al., 1954; Bellman and Dreyfus, 1962; Veinott, 1964)
  - ▶ Lot sizing (Tamir, 1980)
  - ► Assortment with downward substitution (Hanssmann, 1957; Sadowski, 1959; Pentico, 2008)
  - ► Telecommunications (Padakandla and Sundaresan, 2009a)

#### $\epsilon$ -approximate solutions

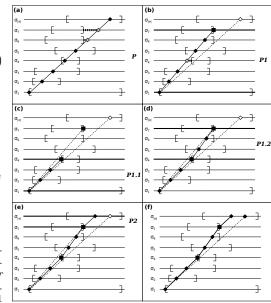

- Computational complexity of algorithms for general non-linear optimization problems ⇒ an infinite output size may be needed due to real optimal solutions.
- To circumvent this issue
  - Existence of an oracle which returns the value of  $f_i(x)$  in O(1)
  - ▶ Approximate notion of optimality (Hochbaum and Shanthikumar, 1990):
    - a continuous solution  $\mathbf{x}^{(\epsilon)}$  is  $\epsilon$ -accurate iff there exists an optimal solution  $\mathbf{x}^*$  such that  $||(\mathbf{x}^{(\epsilon)} \mathbf{x}^*)||_{\infty} \leq \epsilon$ .
  - ▶ Accuracy is defined in the solution space, in contrast with some other approximation approaches which considered objective space (Nemirovsky and Yudin, 1983).

# Existing algorithms – VRP or ship routing literature

- Recursive smoothing algorithm (Norstad et al., 2011; Hvattum et al., 2013)
  - ► Applicable only when the cost/speed functions are arc-independent
  - ► This case is strongly polynomial (which even never needs to evaluate the objective function)
  - Complexity :  $O(n^2)$

Image from R. Kramer, A. Subramanian, T. Vidal, and L. A. F. Cabral. A matheuristic approach for the Pollution-Routing Problem. 2014.

arXiv: 1404 4895v1

# Existing algorithms – VRP or ship routing literature

• And this approach is closely related to the concept of *string method* (Dantzig 1971 and other earlier contributions)

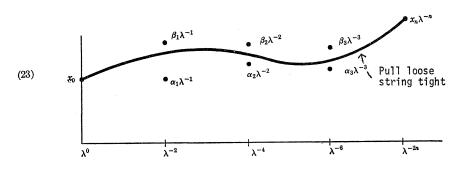

Image from G. B. Dantzig. A control problem of Bellman. Management Science. 17(9), pp. 542-546, 1971.

# Existing algorithms – VRP or ship routing literature

- Dynamic programming approach for the case of piecewise linear and convex functions (Hashimoto et al., 2006)
- Compute recursively the functions  $F_i(b)$  which evaluate the minimum cost to execute the *i* first activities  $(x_1, \ldots, x_i)$  with a resource consumption of *b*.
- Bi-directional dynamic programming can be used. An efficient way to solve serial problems with different (but similar) sequences, using pre-processing and incremental evaluation of moves.

#### Existing algorithms – Others

>

• Dual-inspired methods. Rely on the fact that the continuous resource allocation problem without nested constraints (2.16) can be solved by finding the zero of a single Lagrangian equation:

$$L'_{\text{RAP}}(\lambda) = \sum_{i=v}^{w} \bar{x}_i(\lambda) - B = 0$$
with  $\bar{x}_i(\lambda) = f'_i^{-1} \left( \max(f'_i(0), \min(\lambda, f'_i(d_i))) \right)$ 
(2.18)

- Iteratively solving Lagrangian equations and adjusting violated nested constraints by variable setting.
  - ▶ Padakandla and Sundaresan (2009a): complexity of  $O(n^2\Phi_{RAP}(n, B))$
  - ▶ Wang (2014): complexity of  $O(n^2 \log n + n\Phi_{RAP}(n, B))$
  - ▶ where  $\Phi_{RAP}(n, B)$  is the complexity of solving one RAP with n tasks, e.g., by bisection search.

## Existing algorithms – Others

- A greedy method with scaling for NESTED with integer variables (Hochbaum, 1994)
  - ► **Greedy** algorithms iteratively consider all feasible increments of one resource, and select the least-cost one.
  - ▶ Convergence guarantee (Federgruen and Groenevelt, 1986) to the optimum of the integer RAP in the presence of polymatroidal constraints.

#### • Scaling.

- ▶ An initial problem is solved with large increments
- ► The increment size is iteratively divided by two to achieve higher accuracy.
- ▶ At each iteration, and for each variable, only one increment from the previous iteration may require to be corrected.
- ► Complexity of  $O(n \log n \log \frac{B}{n})$  for NESTED with integer variables

## Proximity theorem

• Proximity Theorem (Hochbaum, 1994):

#### Theorem

For any optimal continuous solution  $\mathbf{x}$  of NESTED, there exists an optimal solution  $\mathbf{z}$  of the same problem with integer variables, such that  $\mathbf{z} - \mathbf{e} < \mathbf{x} < \mathbf{z} + n\mathbf{e}$ , and thus  $||\mathbf{z} - \mathbf{x}||_{\infty} \le n$ . Reversely, for any integer optimal solution  $\mathbf{z}$ , there exists an optimal continuous solution such that  $||\mathbf{z} - \mathbf{x}||_{\infty} \le n$ .

#### Corollary

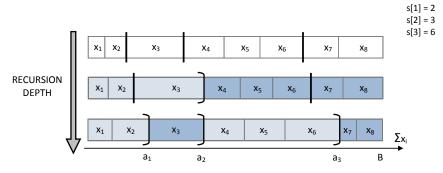

To obtain an  $\epsilon$ -approximate solution of the NESTED problem with continuous variables, it is possible to solve a scaled NESTED problem with integer variables, in which all problem parameters have been multiplied by  $\lceil \frac{n}{\epsilon} \rceil$ .

- Simple divide and conquer framework: to solve a NESTED(v, w) subproblem, first solve NESTED(v, t) and NESTED(t+1, w), and use this information to solve more efficiently the original problem.
- But how to use the information from subproblems...

• First an initialization step and feasibility check, then the main loop of the algorithm is the following:

#### **Algorithm 1** Nested(v, w)

```
1: if v = w then
           (x_{s\lceil v-1 \rceil+1}, \ldots, x_{s\lceil v \rceil}) \leftarrow \text{Rap}(v, v)
 3:
      else
 4:
            Solve two subproblems:
 5:
            t \leftarrow \lfloor \frac{v+w}{2} \rfloor
 6:
            (x_{s[v-1]+1}, \ldots, x_{s[t]}) \leftarrow \text{Nested}(v, t)
 7:
           (x_{s[t]+1},\ldots,x_{s[w]}) \leftarrow \text{Nested}(t+1,w)
 8:
 9:
            DO SOMETHING TO SOLVE THE UPPER LEVEL:
10:
            for i = s[v-1] + 1 to s[t] do
11:
                (\bar{c}_i, \bar{d}_i) \leftarrow (0, x_i)
12:
            for i = s[t] + 1 to s[w] do
13:
                (\bar{c}_i, \bar{d}_i) \leftarrow (x_i, d_i)
            (x_{s\lceil v-1 \rceil+1}, \ldots, x_{s\lceil w \rceil}) \leftarrow \operatorname{Rap}(v, w)
14:
```

• Claim: the algorithm Nested(v, w) is a valid divide-and-conquer approach which returns the optimal solution of the following model:

• Claim: the algorithm Nested 
$$(v,w)$$
 is a valid divide-and-conquer approach which returns the optimal solution of the following model: 
$$\begin{cases} \min & \sum_{i=s[v-1]+1}^{s[w]} f_i(x_i) \\ \text{s.t.} & \sum_{k=s[v-1]+1}^{s[i]} x_k \leq \bar{a}_i - \bar{a}_{v-1} & i \in \{v,\dots,w-1\} \\ & \sum_{i=s[v-1]+1}^{s[w]} x_i = \bar{a}_w - \bar{a}_{v-1} \\ & 0 \leq x_i \leq d_i & i \in \{s[v-1]+1,\dots,s[w]\} \end{cases}$$
 > Research context. Problem statement. Methodology. Remark. Experiments. Conclusions. References. 29/5

• RAP(v, w) is a simple resource allocation problem with updated bounds.

$$\operatorname{RAP}(v, w) \begin{cases} \min & \sum_{i=s[v-1]+1}^{s[w]} f_i(x_i) \\ & \text{s.t.} & \sum_{i=s[v-1]+1}^{s[w]} x_i = \bar{a}_w - \bar{a}_{v-1} \\ & \hat{c}_i \leq x_i \leq \hat{d}_i \end{cases} \qquad i \in \{s[v-1]+1, \dots, s[w]\}$$

- Any classic method can be used to solve this problem.
  - ▶ Integer variables :  $O(n \log \frac{B}{n})$  by Frederickson and Johnson (1982)
  - ▶ Continuous variables : can use bisection search on the Lagrangian dual

## Convergence

#### Theorem

**DEPTH** 

>

Consider (v, t, w) s.t.  $1 \le v \le t \le w \le m$  and v < w. Let  $(x_{s[v-1]+1}^{\downarrow *}, \dots, x_{s[t]}^{\downarrow *})$  and  $(x_{\mathfrak{s}[t]+1}^{\uparrow *}, \ldots, x_{\mathfrak{s}[w]}^{\uparrow *})$  be optimal integer solutions of Nested(v, t) and Nested(t+1, w), then Nested(v, w) admits an optimal integer solution  $(x_{s[v-1]+1}^{**}, \dots, x_{s[w]}^{**})$  such that

$$x_i^{**} \le x_i^{\downarrow *}$$
  $i \in \{s[v-1]+1, \dots, s[t]\}$  (3.1)

$$x_i^{**} \ge x_i^{\uparrow *}$$
  $i \in \{s[t] + 1, \dots, s[w]\}$  (3.2)

Хз X4 **X**5 X7 X۶ RECURSION X<sub>1</sub>  $X_2$  $X_3$  $X_4$ X<sub>5</sub> X6 X7 Xx  $X_1$  $X_2$  $X_3$ XΔ Xς X6  $a_1$  $a_2$ В a<sub>2</sub>

s[1] = 2s[2] = 3s[3] = 6

## Convergence

#### Theorem

>

Consider (v,t,w) s.t.  $1 \le v \le t \le w \le m$  and v < w. Let  $(x_{s[v-1]+1}^{\downarrow *}, \dots, x_{s[t]}^{\downarrow *})$  and  $(x_{s[t]+1}^{\uparrow *}, \dots, x_{s[w]}^{\uparrow *})$  be optimal integer solutions of  $\operatorname{NESTED}(v,t)$  and  $\operatorname{NESTED}(t+1,w)$ , then  $\operatorname{NESTED}(v,w)$  admits an optimal integer solution  $(x_{s[v-1]+1}^{**}, \dots, x_{s[w]}^{**})$  such that

$$x_i^{**} \le x_i^{\downarrow *}$$
  $i \in \{s[v-1]+1,\dots,s[t]\}$  (3.3)

$$x_i^{**} \ge x_i^{\uparrow *}$$
  $i \in \{s[t] + 1, \dots, s[w]\}$  (3.4)

- The valid inequalities (3.3-3.4) can be added to the formulation of Nested (v, w).
- Alone, they guarantee that nested constraints are satisfied
   ⇒ nested constraints can thus be eliminated.
- This leads to a RAP(v, w) with updated bounds which can be efficiently solved.

# Convergence

- Proof of this theorem, in the integer case, using the properties of the greedy algorithm
- For continuous variables, use the proximity theorem of Hochbaum (1994) with a suitable scaling coefficient.
- Alternatively, the KKT conditions can be used for a different proof by contradiction, but need of strong convexity and differentiability (not needed in the first proof).

# Complexity

#### Theorem

The proposed decomposition algorithm for NESTED with integer variables works with a complexity of  $O(n \log m \log \frac{B}{n})$ .

- ▶ In the continuous case, an ε-approximate solution is obtained in  $O(n \log m \log \frac{B}{\epsilon})$  operations
- ▶ For quadratic NESTED, an overall complexity of  $O(n \log m)$  is achieved, using Brucker (1984) or Maculan et al. (2003) for the quadratic RAP sub-problems

# A remark on the expected number of active constraints

- Assume random-generated problem instances such that:
  - $d_i = +\infty;$
  - functions  $f_i$  strictly convex and differentiable,  $f_i(x) = \gamma_i h(x/\gamma_i)$
- Define  $\Gamma_i = \sum_{k=1}^i \gamma_k$  for  $i \in \{0, \dots, n\}$ .
- We can show that solving the KKT conditions of NESTED under these assumptions is equivalent to computing the convex hull of the set of points  $\mathcal{P}$  such that

$$\mathcal{P} = \{ (\Gamma_{s[j]}, a_j) \mid j \in \{0, \dots, m\} \}.$$
 (4.1)

# A remark on the expected number of active constraints

# A remark on the expected number of active constraints

- Assume is addition that
  - $\alpha_i = a_{i+1} a_i$  are i.i.d. random variables;
  - $\triangleright$   $\gamma_i$  are i.i.d. random variables independent from the  $\alpha_i$ 's
  - and the vectors  $(\gamma_i, \alpha_i)$  are non-colinear.
- Then the expected number of points on the convex hull grows as  $O(\log m)$  (Baxter, 1961). Equivalently, there are  $O(\log m)$  expected active nested constraints in the solution.
- This has a large practical impact when the complexity of the method depends on the number of active constraints

  - A new decomposition algorithm
  - Convergence and complexity
- 4 A remark on the expected number of active constraints
- **5** Computational experiments

### Metho 1

- To assess the practical performance of the proposed algorithm, we implemented it as well as the three other methods.
  - ► PS09: dual algorithm of Padakandla and Sundaresan (2009b);
  - ▶ W14 : dual algorithm of Wang (2014);
  - ► H94 : scaled greedy algorithm of Hochbaum (1994);
  - ► MOSEK: interior point method of MOSEK (Andersen et al., 2003, for conic quadratic opt.);
  - ► THIS : proposed decomposition method.
- In these tests, we rely on a simple bisection search on the Lagrangian equation to solve the RAP subproblem.

### Metho 1

• Each algorithm is tested on randomly-generated instances of NESTED problems (100 or 10 per type and size) with three families of objective functions.

[F] 
$$f_i(x) = \frac{x^4}{4} + p_i x$$
  $x \in [0, 1]$  (5.1)

[Crashing] 
$$f_i(x) = k_i + \frac{p_i}{x} \qquad x \in [c_i, d_i] \qquad (5.2)$$

[FuelOpt] 
$$f_i(x) = p_i \times c_i \times \left(\frac{c_i}{x}\right)^3$$
  $x \in [c_i, d_i]$  (5.3)

- ▶ Size of instances ranges from n = 10 to 1,000,000.
- Accuracy of  $\epsilon = 10^{-8}$
- ▶ Coded in C++
- ► Tests conducted on a Xeon 3.07 GHz CPU

### Conclusions

- Investigate a particular case of timing problem with flexible travel times, equivalent to a nested resource allocation problem.
- Highlighted a rich variety of applications
- Interesting geometrical properties
- A new polynomial algorithm
  - ▶ matching the state-of-the-art complexity (Hochbaum, 1994) when m = n
  - and improving when  $\log m = o(\log n)$
- Different concepts based on monotonicity properties
- Extensive experimental analyses

# Perspectives

- Resolution of series of problems with different permutations of activities
- Identifying an even richer set of related problems, models and applications
- Further generalizations

# Thank you
