# A Lower Bound for the Quickest Path Problem 

Gianpaolo Ghiani ${ }^{1} \quad$ Emanuela Guer ${ }^{1}$ Department of Engineering for Innovation<br>University of Salento (Italy)

## Route 2014

## Outline

(1) Motivation

- The Quickest Path Problem

2 Our Contribution
(3) The Quickest Path Problem

4 A lower bound
(5) Computational Results

## The Quickest Path Problem

The determination of shortest or quickest paths on road networks is the basic ingredient of driving direction computation as well as of logistic planning and traffic simulation.

## Typical application setting

## THEORY

- Dijkstra Algorithm
- Bidirectional search
- A* (goal-directed)

Phase I: 1959-1999 Phase II : 1999-2005 Phase III: 2005-2008 Phase IV: 2008-....

## SPEED UP TECHNIQUES

- Scultz at al. 99
- goal-directed
- hierarchical approach

In-depth reviews: Delling et al (2009) and Sommer (2012)

## Our Contribution

We can define $\underline{z}(i, d)$ : a lower bound on the minimum travel time from node $i$ to target $d$. This bound can be used in $A^{*}$ algorithm a best first search

$$
h(i, d)=t_{s i}+\underline{z}(i, d)
$$

The Dijkstra's algorithm can be seen as an A* procedure with a null lower bound.

## Our Contribution

We can define $\underline{z}(i, d)$ : a lower bound on the minimum travel time from node $i$ to target $d$. This bound can be used in $A^{*}$ algorithm a best first search

$$
h(i, d)=t_{s i}+\underline{z}(i, d)
$$

In this research work we focus on a new lower bound $\underline{z}(i, d)$ for the Quickest Path Problem (QPP).

## In a nutshell...

## In a nutshell...

## In a nutshell...

We propose a new lower bound that takes into account moderate speed areas

## Our Contribution

- The proposed new lower bound is 3.88 times faster and more effective then the trivial lower bound
- We embeded the new lower bounding procedure into a unidirectional $A^{*}$
- We test the resulting algorithm on some metropolitan areas

## The Quickest Path Problem

- Given a directed graph $\mathrm{G}(\mathrm{V}, \mathrm{A})$. With each $\operatorname{arch}(i, j) \in A$ are associated
- a non negative constant travel time $t_{i j}$,
- a positive length $l_{i j}$ and a speed $\nu_{i j}=l_{i j} / t_{i j}$
- a curve $\Gamma_{i j}$ (i.e. the geometry associated to the road)
- given a source node $s \in V$ and a destination node $d \in V$
- The traversal time $z_{p}$ of a path $\left.p=\left(s=i_{1}, i_{2}, \ldots, i_{k}=d\right)\right)$ is $\sum_{h=1}^{k} t_{i_{h} i_{h+1}}$

We aim to determine a path $p$ such that $z_{p}$ is minimum. Let $z^{*}$ be such minimum duration.

## Problem Relaxation

## Problem Relaxation

## Problem Relaxation

## Problem Relaxation

Given two nodes $i, j \in V$ the path can be any curve in the plane.

## The proposed Lower Bound

Subcurves in $R$ and $\Gamma \backslash R$ are traversed at speeds $\nu^{R}$ and $\nu^{G}$, respectively.

## The proposed Lower Bound

Theorem. A least duration curve from $s$ to $d$ in the plane is a polyline $s-u-v-d$, where $u \in \overline{A B} \cup \overline{A D}$ and $v \in \overline{B C} \cup \overline{C D}$.

Figure 1: First Case

## The proposed Lower Bound

Figure 2: Second Case

- $u$ is the last intersection point with $\overline{A B} \cup \overline{A D}$ saw from $s$
- $v$ is the first intersection point with $\overline{B C} \cup \overline{C D}$ saw from $d$.

## The least duration curves: four types

$$
T(u, v)=\frac{\operatorname{dist}(s, u)}{\nu^{G}}+\frac{\operatorname{dist}(u, v)}{\nu^{R}}+\frac{\operatorname{dist}(v, d)}{\nu^{G}}
$$

Figure 2: Second Case

## The least duration curves: four types

$$
\min _{\substack{u \in \overline{A B} \\ v \in B C}} T(u, v)
$$

$$
\min _{\substack{u \in \overline{A D} \\ v \in B C}} T(u, v)
$$

Figure 4: Path Type 2

## The least duration curves: four types

$$
\min _{\substack{u \in \overline{A D} \\ v \in C D}} T(u, v)
$$

$$
\min _{\substack{u \in \overline{A B} \\ v \in C D}} T(u, v)
$$

Figure 5: Path Type 3

Figure 6: Path Type 4

## The Lower Bound

A lower bound $\underline{z}$ can be computed by solving the following four optimization problems:

$$
\begin{aligned}
& \min _{\substack{u \in \overline{A B} \\
v \in \overline{B C}}} T(u, v) \\
& \min _{\substack{u \in \overline{A D} \\
v \in C D}} T(u, v)
\end{aligned}
$$

$$
\begin{aligned}
& \min _{\substack{u \in \overline{A D} \\
v \in \overline{B C}}} T(u, v) \\
& \min _{\substack{u \in \overline{A B} \\
v \in C D}} T(u, v)
\end{aligned}
$$

and then taking the minimum.

## Type 1 Path

Two-variable non-linear box-constrained optimization problems (time consuming iterative methods)

$$
\min _{\substack{u \in \overline{A B} \\ v \in \overline{B C}}} \frac{\operatorname{dist}(s, u)}{\nu^{G}}+\frac{\operatorname{dist}(u, v)}{\nu^{R}}+\frac{\operatorname{dist}(v, d)}{\nu^{G}}
$$

Figure 3: Path Type 1

## Type 1 Path: a relaxation

Figure 3: Type 1 path

$$
\underline{z}^{1}=\min _{\substack{\leq w \leq w \\ 0 \leq h \leq H}} \frac{y_{B}-y_{s}-h}{\nu^{G}}+\frac{\sqrt{h^{2}+w^{2}}}{\nu^{R}}+\frac{x_{d}-x_{B}-w}{\nu^{G}}
$$

## Type 1 Path: a relaxation

$$
\alpha=\frac{\nu_{G}}{\nu_{R}}>1
$$

```
Algorithm 1 Computing an optimal solution \(\left(w^{*}, h^{*}\right)\) for the Path 1 sub-
problem
if \((\alpha \geq \sqrt{2})\) then
        \(w^{*}=0\);
        \(h^{*}=0\);
    else
        \(w^{*}=\min \left(\frac{H}{\sqrt{\alpha^{2}-1}}, W\right) ;\)
\(h^{*}=H ;\)
        \(h^{*}=H\);
    end if
```

$$
\underline{z}^{1}=\min _{\substack{0 \leq w \leq W \\ 0 \leq h \leq H}} \frac{y_{B}-y_{s}-h}{\nu^{G}}+\frac{\sqrt{h^{2}+w^{2}}}{\nu^{R}}+\frac{x_{d}-x_{B}-w}{\nu^{G}}
$$

$$
\alpha=\frac{\nu_{G}}{\nu_{R}}>1
$$

```
Algorithm 1 Computing an optimal solution \(\left(w^{*}, h^{*}\right)\) for the Path 1 sub-
problem
    if \((\alpha \geq \sqrt{2})\) then
        \(w^{*}=0\);
        \(h^{*}=0 ;\)
    else
        \(w^{*}=\min \left(\frac{H}{\sqrt{\alpha^{2}-1}}, W\right) ;\)
        \(h^{*}=H\);
    end if
```

## Theorem

The solution provided by Algorithm 1 is optimal for the Type 1 path subproblem.

## Theorem

The solution provided by Algorithm 1 is optimal for the Type 1 path subproblem.

## Proof Sketch

We prove that $w^{*}$ and $h^{*}$ satisfy the KKT conditions for the Type 1 path optimization subproblem

## Implementation Issue

Type 1 Path is suitable for a preprocessing phase

$$
\begin{gather*}
\bar{z}^{1}=\bar{z}_{a}^{1}+\left(\frac{y_{s}+x_{d}}{\nu^{G}}\right) ;  \tag{1}\\
\bar{z}_{a}^{1}=\left(\frac{y_{B}-h_{1}^{*}}{\nu^{G}}+\frac{\sqrt{\left(h_{1}^{*}\right)^{2}+\left(w_{1}^{*}\right)^{2}}}{\nu^{R}}+\frac{-x_{B}-w_{1}^{*}}{\nu^{G}}\right) ; \tag{2}
\end{gather*}
$$

where $\bar{z}_{a}^{1}$ does not depend on $s$ and $d$

## Type 1 Path - Type 3 Path

A Type 3 problem is equivalent to a Type 1 problem where $x_{i}$ and $y_{i}$ are swapped for $i \in\{s, d, A, B, C, D\}$.

## Type 2 Path: a relaxation

$$
\begin{equation*}
\underline{z}^{2}=\min _{\substack{0 \leq w \leq W \\ 0 \leq h \leq W}} \frac{x_{A}-x_{s}+h}{\nu^{G}}+\frac{\sqrt{H^{2}+(w-h)^{2}}}{\nu^{R}}+\frac{x_{d}-x_{B}-w}{\nu^{G}} \tag{3}
\end{equation*}
$$

$$
\alpha=\frac{\nu_{G}}{\nu_{R}}>1
$$

```
Algorithm 2 Computing an optimal solution \(\left(w^{*}, h^{*}\right)\) for the Path 2 sub-
problem
    \(h^{*}=0 ;\)
    \(w^{*}=\frac{H}{\sqrt{\alpha^{2}-1}} ;\)
    if \(\left(w^{*}>W\right)\) then
        \(w^{*}=W\)
    end if
```

## Theorem

The solution provided by Algorithm 2 is optimal for the Type 2 path subproblem.

## Implementation Issue

Type 2 Path is suitable for a preprocessing phase

$$
\begin{gather*}
\bar{z}^{2}=\bar{z}_{a}^{2}+\left(\frac{-x_{s}+x_{d}}{\nu^{G}}\right) ;  \tag{4}\\
\bar{z}_{a}^{2}=\left(\frac{x_{A}+h_{2}^{*}}{\nu^{G}}+\frac{\sqrt{H^{2}+\left(w_{2}^{*}-h_{2}^{*}\right)^{2}}}{\nu^{R}}+\frac{-x_{B}-w_{2}^{*}}{\nu^{G}}\right) ; \tag{5}
\end{gather*}
$$

where $\bar{z}_{a}^{2}$ does not depend on $s$ and $d$

## Type 2 Path - Type 4 Path

A Type 4 problem is equivalent to a Type 2 problem where $x_{i}$ and $y_{i}$ are swapped for $i \in\{s, d, A, B, C, D\}$.

## The Lower Bounding Algorithm

$$
\begin{aligned}
& \bar{z}^{1}=\bar{z}_{a}^{1}+\left(\frac{y_{s}+x_{d}}{\nu^{G}}\right) \\
& \bar{z}^{2}=\bar{z}_{a}^{2}+\left(\frac{-x_{s}+x_{d}}{\nu^{G}}\right) \\
& \bar{z}^{3}=\bar{z}_{a}^{3}+\left(\frac{x_{s}+y_{d}}{\nu^{G}}\right) \\
& \bar{z}^{4}=\bar{z}_{a}^{4}+\left(\frac{-y_{s}+y_{d}}{\nu^{G}}\right) \\
& \underline{z}=\min \left\{\underline{z}^{1}, \underline{z}^{2}, \underline{z}^{3}, \underline{z}^{4}\right\}
\end{aligned}
$$

## Computational Results

The lower bounding procedures were coded in C++ and embedded into a unidirectional $A^{*}$ algorithm implementation of Boost Graph Library.

The codes were run on a PC with a 2.53-GHz Intel Core 2 Duo processor and 4 GB of memory.

## Computational Results

We made use of three road networks of large European metropolitan area (OpenStreetMap)

- Paris about 113,000 arcs
- Madrid about 96,000 arcs
- Rome about 52,000 arcs

For each graph we identified $n_{R}$ (possibly overlapping) rectangles with $\nu^{R}$ equal to $50 \mathrm{~km} / \mathrm{h}$.

We randomly generated 1500 origin-destination pairs

- Type a: neither sor $d$ are located inside a rectangle; moreover the segment $s-d$ does not intercept any rectangle;
- Type $b$ : either $s$ or $d$ (but not both) are located inside a rectangle;
- Type $c: s$ and $d$ are located inside different rectangles;
- Type $d: s$ and $d$ are located inside the same rectangle;
- Type $e$ : neither $s$ or $d$ are located inside a rectangle; however, the segment $s-d$ intercepts at least a rectangle.

## Type a: 300 randomly generated origin-destination pairs

## Type b: 300 randomly generated origin-destination pairs

## Type c: 300 randomly generated origin-destination pairs

## Type d: 300 randomly generated origin-destination pairs

## Type e: 300 randomly generated origin-destination pairs

- $L B_{E} / z^{*}=0.487, L B / z^{*}=0.515$
- The new lower bounding procedure is 3.88 times faster than Euclidean procedure (thanks to preprocessing phase)
- Average reduction of $28.87 \%$ in the number of nodes visited by $\mathrm{A}^{*}$ (which is independent of the implementation)
- Average reduction in computing time is $14.36 \%$ (This speed-up is valuable for a typical web application setting)
- $L B_{E} / z^{*}=0.487, L B / z^{*}=0.515$

# - For type $d$ and $c$ instances (i.e., whenever the origins and destinations are inside an area with moderate speeds) we obtained even greater computing time reductions (up to 28.06\%). 

- For type $d$ and $c$ instances (i.e., whenever the origins and destinations are inside an area with moderate speeds) we obtained even greater computing time reductions (up to 28.06\%).

## Future Research

- Lower bounding procedure integrated into bidirectional $\mathrm{A}^{*}$
- Quick procedures for the selection of good rectangles (we used a simple heuristic)
- Combine our approach with the most recent speed-up techniques.
- Time-Dependent Scenario
